contracts benchmarking and evaluation

Chainspace: A Sharded Smart Contracts Platform

Abstract—Chainspace is a decentralized infrastructure, known as a distributed ledger, that supports user defined smart contracts and executes user-defined operations on their objects. The correct execution of smart contract functions is verifiable at all. The system is scalable, by sharding state and the execution of transactions, and using S-BAC, a distributed commit protocol, to guarantee consistency. Chainspace is secure against sets of nodes that can compromise its integrity and availability protocol through Byzantine Fault Tolerance (BFT), and extremely high-audibility, non-repudiation and ‘blockchain’ techniques. Even when nodes fail, users are in control to verify the correctness of consensus participants. We present the design rationale and details of Chainspace; we argue through evaluating an implementation of the system about its scaling and other features; we illustrate a number of privacy-friendly smart contracts for smart metering, polling and banking and measure their performance.

I. INTRODUCTION

Chainspace is a distributed ledger platform for high-integrity and transparent processing of transactions within a decentralized system. Unlike application specific distributed ledgers, such as Bitcoin [Nak08] for a currency, or certificate transparency [Lam13] for certificates, Chainspace is open to composing off-chain generic smart contracts, like Ethereum [Wei14]. However, users expose to Chainspace enough information about contracts and transaction semantics, to provide higher scalability through sharding across infrastructure nodes: our nodes process up to 60 transactions per second, and 1000 per second, as compared with a peak rate of less than 7 transactions per second for Bitcoin over 6K full nodes. Ethereum currently processes 4 transactions per second, out of theoretical maximum of 25. Furthermore, our platform is agnostic as to the smart contract language, or identity infrastructure, and supports privacy, through modern zero-knowledge techniques [BCCG16, DGEK14].

Unlike other available but ‘permissioned’ smart contract platforms, such as Hyperledger Fabric [CaCo16] or BigchainDB [MMM+16], Chainspace aims to be an ‘open’ system: it allows anyone to author a smart contract, anyone to provide infrastructure on which smart contract code and state runs, and any user to access cells to smart contracts. Further, it provides ecosystem features, by allowing composition of smart contracts from different authors. We integrate a value

system, named CSCoin, as a system smart contract to allow for accounting between those parties.

However, the security model of Chainspace, is different from traditional unpermissioned blockchains, that rely on proof-of-work and global replication of state, such as Ethereum. In Chainspace smart contract authors designate the parts of the infrastructure that are responsible for the integrity of the contract—and only depend on their correctness, as well as the correctness of contract sub-cells. This provides fine grained control of which part of the infrastructure need to be trusted on a per-contract basis, and also allows for horizontal scalability.

This paper makes the following contributions:

- It presents Chainspace, a system that can scale arbitrarily as the number of nodes increase, tolerates byzantine failures, and can be fully and publicly audited.
- It presents a novel distributed atomic commit protocol, called S-BAC, for sharding generic smart contract transactions across multiple byzantine nodes, and correctly coordinating those nodes to ensure safety, liveness and security properties.
- It introduces a distinction between parts of the smart contract that execute a computation, and those that check the computation and discusses how that distinction is key to supporting privacy-friendly smart-contracts.
- It provides a full implementation and evaluates the performance of the byzantine distributed commit protocol, S-BAC, on a real distributed set of nodes and under varying transaction loads.
- It presents a number of key system and application-specific smart contracts and evaluates their performance. The contracts for privacy-friendly smart-metering and privacy-friendly polls illustrate and validate support for high-integrity and high-privacy applications.

Outline: Section II presents an overview of Chainspace; Section III presents the client-facing application interface; Section IV presents the design of internal data structures guaranteeing integrity, the distributed architecture, the byzantine commit protocol, and smart contract definition and composition. Section V presents the implementation and describes smart contracts and their evaluations presented in Section VI; Section VII presents an evaluation of the core protocols and smart contract performance; Section VIII presents limitation and Section IX a comparison with related work; and Section X concludes.

Future Works

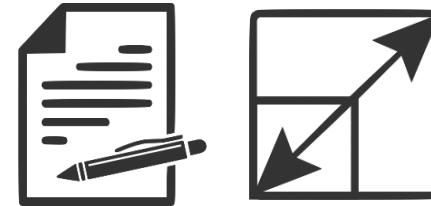

- 1. How to recover from malicious shards?**
- 2. How can a smart contract creator avoid dishonest shards ?**
- 3. How to configure shards?**
- 4. How to incentivise nodes?**
